## **Bacterial Mutation - an overview | ScienceDirect Topics**

Mutation is a process that produces a gene or chromosome that differs from the wild type (arbitrary standard for what “normal” is for an organism). It is most commonly defined as a spontaneous permanent change in a gene or chromosome which usually produces a detectable effect in the organism concerned and is transmitted to the offsprings.

Mutations are one way for bacteria to become resistant to antibiotics. Some spontaneous mutations (or genes that have been acquired from other bacteria through horizontal gene transfer ) may make the bacterium resistant to an antibiotic (See: Resistance mechanisms

## **Mutations and selection - Antibiotic resistance - ReAct**

The remarkable capacity of some viruses to adapt to new hosts and environments is highly dependent on their ability to generate de novo diversity in a short period of time. Rates of spontaneous mutation vary amply among viruses. RNA viruses mutate faster than DNA viruses, single-stranded viruses mutate faster than double-strand virus, and genome size appears to correlate negatively with ...

In time, this reduction can be compensated by mutations in other loci of the bacterial chromosome (5, 10, 66), so that the antibiotic-resistant bacteria can present a level of fitness equal to or even higher than those of the original wild-type strains. If the mutant

## **Mutation Frequencies and Antibiotic Resistance**

Mutations result from errors during DNA replication, mitosis, and meiosis or other types of damage to DNA (such as pyrimidine dimers that may be caused by exposure to radiation or carcinogens), which then may undergo error-prone repair (especially microhomology-mediated end joining) or cause an error during other forms of repair or else may cause an error during replication (translesion synthesis).

Mechanisms include interference with cell wall synthesis (e.g., beta-lactams and glycopeptide agents), inhibition of protein synthesis (macrolides and tetracyclines), interference with nucleic acid synthesis (fluoroquinolones and rifampin), inhibition of a metabolic pathway (trimethoprim-

## **Mechanisms of antimicrobial resistance in bacteria**

Point mutations may be of four different types— transition, trans-version, insertion and deletion. In a transition mutation, a purine base is replaced by another purine and a pyrimidine by another pyrimidine e.g. an A-T base-pair is replaced by a G-C base-pair and vice versa.

A mutation is a heritable change in the DNA sequence of an organism. The resulting organism, called a mutant, may have a recognizable change in phenotype compared to the wild type, which is the phenotype most commonly observed in nature. A change in the DNA sequence is conferred to mRNA through transcription, and may lead to an altered amino acid sequence in a protein on translation.

Even though we now accept that bacteria evolve through Darwinian mechanisms, 'quasi-Lamarckian' processes of bacterial evolution are still being discovered and debated 4 - 6.

There are three possible mechanisms for transferring a trait from B to A: (1) transformation, release and uptake of naked DNA; (2) transduction, packaging and transfer of bacterial DNA by viruses, and (3) conjugation, bacterial mating in which cells must be in contact.
