The Angiosome Concept And Tissue

The concept is an interpretation of the vascular anatomy of the body as the basis for tissue transfer and the explanation of various pathological processes. Part history, part anatomical atlas, and part clinical application, this major reconstructive work is a virtual treasure trove of important historical, anatomical, and clinical pearls from one of the true masters of reconstructive surgery.

Plastic Surgery | The Angiosome Concept and Tissue Transfer

The two-volume set entitled The Angiosome Concept and Tissue Transfer, by G. Ian Taylor and co-author Wei-Ren Pan, gathers this tremendous body of work and presents it along with a historical perspective on the development of tissue transfer techniques and an in-depth discussion of the clinical applications of the angiosome concept.

The Angiosome Concept and Tissue Transfer: Volumes 1 and 2 ...

The angiosome concept delineates the human body into three-dimensional blocks of tissue fed by specific arterial and venous sources named "angiosomes." Adjacent angiosomes are connected by a vast compensatory collateral web, or "choke vessels." This concept may provide new information applicable to improving targeted revascularization of ischemic tissue lesions.

The angiosome concept was derived from plastic surgery for the purpose of healing of skin flaps. 4 An angiosome is an anatomic unit of tissue (consisting of skin, subcutaneous tissue, fascia, muscle, and bone) fed by a source artery and drained by specific veins. The entire body can be divided into 40 angiosomes, and the foot itself consists of six.

• The angiosome (from the Greek angeion, meaning vessel, and somite, meaning segment or sector of the body derived from soma, body) is defined as a composite block of tissue supplied by a main source artery. The source arteries (segmental or distributing arteries) that supply these blocks of tissue are responsible for the supply of the skin and the underlying deep structures.

Angiosome concept - SlideShare

2. The angiosome concept. The angiosome concept has been conceived based on anatomical studies in plastic reconstructive surgery . The term angiosome is derived from the Greek angio- meaning vessel, and somite meaning segment or sector of the body (derived from soma meaning body). These studies identified three-dimensional blocks of tissue (consisting of skin, subcutaneous tissue, fascia, muscle, and bone) that are perfused and drained by specific angiosomal vessels.

The angiosome model of reperfusion can be applied to planning incisions and tissue exposures that preserve blood flow for surgical wounds to heal and predicting which pedicled flap can be successfully harvested or whether a particular amputation will heal. 18 It can also help in choosing whether a bypass or an endovascular procedure has the ...

The Angiosome Concept - Endovascular Today

In 1987, Taylor and Palmer introduced the angiosome concept. This anatomical study defined the three-dimensional vascular territories supplied by source arteries and veins to each tissue layer between the skin and the bone. This report, however, was an overview investigation and did not study each region of the body in fine detail.

METHODS: The angiosome concept, published in 1987, was reviewed and correlated with key experimental and clinical work by the authors, published subsequently at different times in different journals. In addition, new data are introduced to define these anatomical and clinical territories of the cutaneous perforators and to aid in the planning ...

This angiosome concept has generated great interest, with studies extrapolating this model on the treatment of patients with critical leg ischemia (CLI) and tissue healing. In 2006, Attinger et al 2 published their study looking into the clinical implications of foot and ankle angiosomes on revascularization and limb salvage.

As may be obvious from its name, one of the major functions of connective tissue is to connect tissues and organs. Unlike epithelial tissue, which is composed of cells closely packed with little or no extracellular space in between, connective tissue cells are dispersed in a matrix.The matrix usually includes a large amount of extracellular material produced by the connective tissue cells that ...
